

SOFTWARE ENGINEERING LAB 2

Name: Nidhi S

SRN: PES1UG24AM919

Section: G

SCREENSHOTS:

1. Jira backlog with Epics and User Stories:

2. Active sprint 1 with story point assignments:

3. Sprint board (Active Sprint view): todo, in progress, done:

4. Burndown chart for sprint 1:

5. Active sprint 2 view—todo, in progress, done:

6. Burndown chart for sprint 2:

Note: Sprint 2's guideline didn't render due to the compressed simulation timeframe

Reflection Questions – Lab 2: Agile Backlog Creation & Sprint Simulation

1. Did your estimations reflect the actual effort?

Since this was a simulated sprint rather than real development work, the story points (assigned using the Fibonacci scale: 2, 3, 3, 3, 5, 5, 5, 8) reflected our *relative* judgment of complexity rather than actual time spent completing each story. For example, "Automatic Supplier PO Dispatch" was estimated at 8 points because it depends on both inventory verification and address handling, making it the most complex story in the backlog. In a real sprint, tracking actual hours against these estimates over multiple sprints would be needed to validate whether the point values were accurate.

2. Was your backlog well-prioritized?

Yes. The backlog was prioritized by business impact: Epic 1 (Order Intake & Auto-Dispatch) and Epic 2 (Multi-Vendor Order Splitting) were marked High priority and placed in Sprint 1, since without automated order parsing and correct order splitting, no other part of the system can function. Epic 3 (Shipment Tracking) and Epic 4 (Stockout Handling & Resilience) were marked Medium and scheduled for Sprint 2, as they add reliability and visibility but depend on the core order pipeline being in place first.

3. How did your simulated sprint align with your plan?

Sprint 1 (21 points: Epics 1 & 2) and Sprint 2 (13 points: Epics 3 & 4) both completed all planned stories, moving them through To Do → In Progress → Done as intended. Since this was a simulation rather than a real week of work, all stories were completed within a short compressed timeframe instead of being spread across the full sprint duration, which is the main way this diverged from how a real sprint would run.

4. What insights did the burndown chart give about your team's capacity?

The burndown chart for Sprint 1 showed the "Remaining Values" line dropping sharply at the very start rather than following the grey guideline's gradual daily slope. In a real sprint, this pattern would usually signal that the team finished work far faster than planned, suggesting the sprint was under-loaded relative to the team's actual capacity. In our case, it was a direct result of simulating the sprint in minutes rather than over a full week. This highlighted why burndown charts are only meaningful when tracked against real elapsed time — a compressed simulation can't reveal genuine velocity or capacity insights the way an actual multi-day sprint would.
